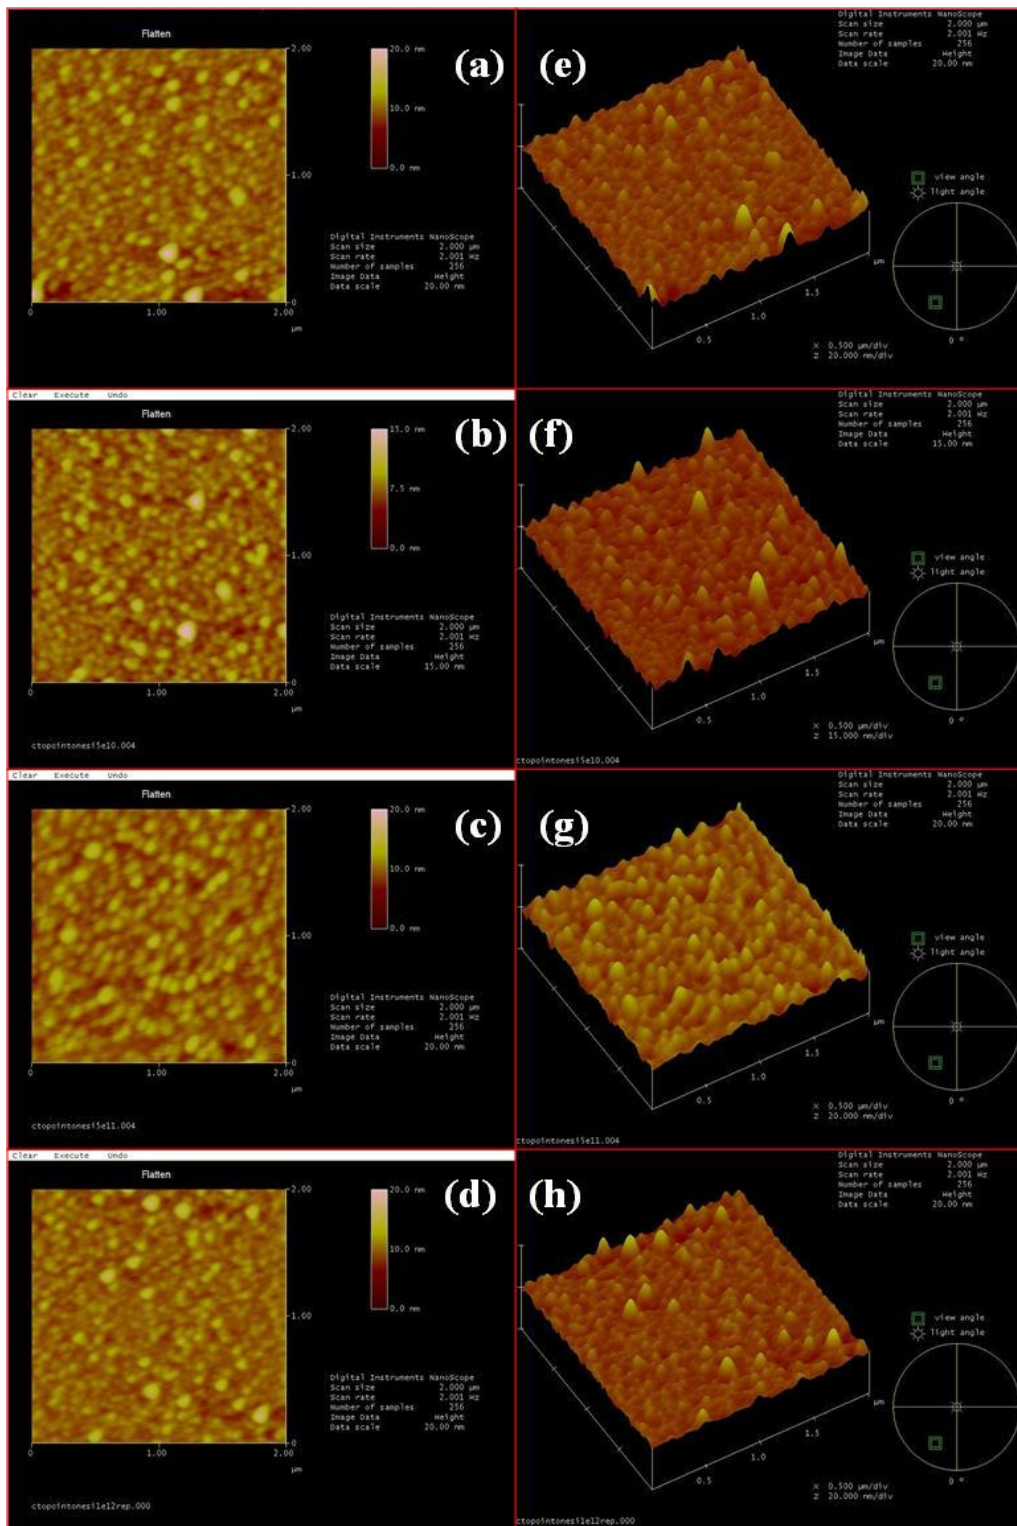

**Fig. 7.3** XRD patterns of CZTF at various pressures and temperatures. The patterns are recorded at different pressures (0.1 mTorr, 1 mTorr, 300 mTorr) and temperatures (5E10, 5E11, 1E12) for different samples (5E10, 5E11, vacuum). The asterisk (\*) indicates a peak that is not indexed to the R phase. The R (110), R (210), and A (004) peaks are observed at different pressures and temperatures.

**Fig.7.10** XRD patterns of  $\text{NiCrQ}_5$  and  $\text{NiCrQ}_4$  samples. The patterns are stacked vertically for samples 1E13, 1E12, 1E11, and 1E0. The x-axis represents the diffraction angle  $2\theta$  in degrees, ranging from 20 to 70. The y-axis represents Intensity in arbitrary units. Peaks are labeled with 'S' and '(004)'. The patterns show characteristic peaks for the samples, with the (004) peak being prominent in all cases.

**Fig.7.13** (a) Magnetization curves for  $\text{Ti}_{0.95}\text{Co}_{0.05}\text{O}_{2-\delta}$  at 0.1 mTorr for various ion concentrations:  $1 \times 10^{12}$ ,  $1 \times 10^{11}$ , and  $1 \times 10^{13}$  ions/cm<sup>2</sup>, and Pristine. (b) Magnetization curves for  $\text{TiO}_{2-\delta}$  at 0.1 mTorr for an ion concentration of  $1 \times 10^{11}$  ions/cm<sup>2</sup> and Pristine. ZFC and FC curves are shown for each case.

**Fig.7.14** (a) Magnetization curves for CTO film at 300 K and (b) CTO at 5 K, both measured at 0.1 mTorr. The curves show the effect of increasing the concentration of the dopant (1E11, 1E12, 1E13) on the magnetization. The saturation magnetization increases with the dopant concentration. The temperature T = 300 K and T = 5 K are indicated in the plots.

**Fig.7.15** (a) Magnetization curves of TiO<sub>2</sub> at 300 K for different concentrations of Fe ions (1E11, 1E12, 1E13) and (b) at 5 K. The inset shows the zoomed-in view of the low-field region. The data points are fitted with a Brillouin function. The saturation magnetization increases with the concentration of Fe ions.

### 7.3.3 Transport and Magneto-transport Properties

This type of existence of both BMP and RKKY models in dilute magnetic oxides have been proposed theoretically by Calderon and Sarma (2007, 2007 (a)). With ion irradiation the films become insulating leading to decrease in number of delocalized electrons and favour the formation of BMPs. Consequently, the minima in resistivity disappear whereas RKKY mechanism ceases and the BMP model may be operative to give rise to the ferromagnetic order.

#### 7.4 Summary

- We have studied the evolution of structure and magnetic properties creating further defects in TiO<sub>2</sub> and CTO thin films deposited on Si and LaAlO<sub>3</sub> substrate by irradiating with 100 MeV Ag<sup>7+</sup> ions varying ion fluence from  $1 \times 10^{11}$  to  $1 \times 10^{13}$  ions.cm<sup>-2</sup>.
- While the film deposited on Si substrate under 0.1 mTorr oxygen partial pressure retains its crystallinity showing radiation-resistant behaviour even at a fluence of  $1 \times 10^{12}$  ions.cm<sup>-2</sup>, films deposited under 1 to 300 mTorr oxygen partial pressure become almost amorphous at the same fluence.
- Using Poisson's law while the diameter of the amorphized region surrounding the ion path is calculated to be ~ 4.2 nm from XRD peak intensity ((1 1 0) for rutile phase) as a function of ion fluence, from saturation magnetization (M<sub>s</sub>) measurement, magnetic disordered region surrounding the ion path is found to be ~ 6.6 nm which is larger than the diameter of the amorphized latent track.
- We show here that swift heavy ion irradiation induces significant magnetic disorder than the structural disorder surrounding the ion path.
- After irradiating with 100 MeV Ag<sup>7+</sup> ions in both TiO<sub>2</sub> and Ti<sub>0.95</sub>Co<sub>0.05</sub>O<sub>2-δ</sub> films grown on LaAlO<sub>3</sub> substrate, the anatase structure is retained. Temperature dependence of resistivity of pristine TiO<sub>2</sub> and Ti<sub>0.95</sub>Co<sub>0.05</sub>O<sub>2-δ</sub> films deposited at 0.1 mTorr oxygen partial pressures and irradiated with

fluence  $1 \times 10^{11}$  ions.cm<sup>-2</sup> exhibit metallic behaviour having a resistivity minima below room temperature.

- Although, the resistivity data below minima have been fitted using the proposed Kondo scattering model as well as quantum corrections to conductivity (QCC) model with appreciable fitting parameters in both the cases, the observation of ferromagnetism below  $T_{\min}$  eliminates the Kondo effect.
- Therefore, low temperature resistivity behaviour in  $\text{Ti}_{1-x}\text{Co}_x\text{O}_{2-\delta}$  films is discussed on the basis of QCC model as proposed for the disordered electronic systems.
- The ferromagnetism obtained with lower fluence with different  $M_s$  value while governed by the competing Ruderman-Kittel-Kasuya-Yosida (RKKY) and bound magnetic polaron (BMP) mechanisms, the maximum  $M_s$  obtained in the films irradiated at  $1 \times 10^{13}$  ions.cm<sup>-2</sup> is explained on the basis of BMP model only.
